

You can always find a late version of the draft here, if you don't like to make things.

Basic flow and questions

Fig 1 is the kappa and extra realized variation stuff, it seems cool, maybe could be expanded upon

Fig 2 is the baseline Roswell-conjecture stuff. JD likes it more (and could maybe talk about it more?) but Roswell and Weitz think it's not actionable enough so we've been playing with other stuff

Current Fig 3 shows what you would think about realized infections if you only had information up to a certain point. Maybe prevalence is a better fit for panel A here? What about a cumulative incidence? But we do want to show the rescaled incidence as well; that goes well with Current S2

Current Fig 4 shows all information (including future information) about cohorts infected up to a certain point. Since we wind up talking mostly about cohorts, maybe Current Fig S2 would be better here? Maybe cumulative incidence is a better fit for panel A here?

Fig S1 is clearly useful and shows connection to real time. JD is wondering if there is room for prevalence curves as well.

Fig S2 shows maybe a simpler way of thinking about F4, but we could also ask about keeping it relatively simple and putting both 3 and 4 in Supp? JD suspects Maryland may have counter-arguments.

Thoughts

Keep F1 and F2

What do we have to illustrate the balancing

Promote S1 and S2, use them to illustrate quickness point

Do we need another figure, and can it be based on F3?

F3 has a new proof, do we need it?

Is F4 more practical
